

# 1 Spinning Block and Hanging Weight using Lagrange Multiplier

A block, with mass  $m$ , slides without friction on a level table. A stretch-less, massless string connects this block to a hanging weight, with mass  $M$ , through a hole in the table. The block on the table can orbit around the table so that the angle  $\theta$  and the radial distance  $r$  both change with time. When  $r$  changes the distance from the table to the hanging weight,  $x$ , changes too. This gives us the constraint equation  $f = r + x - a = 0$ , where  $a$  is a constant. Consider your dynamical (generalized coordinate) variables to be  $\theta$ ,  $r$ , and  $x$ .

## 1.1 Find Equations of Motion

Find the equations of motion for  $\theta$ ,  $r$ , and  $x$  using a Lagrange multiplier  $\lambda$ , with the given constraint equation. You do not have to solve them, or solve for  $\lambda$ .

## 1.2 Remove the $\dot{\theta}$ Dependence in the $r$ Equation

The integration constant for the  $\theta$  equation is the angular momentum of the block about the hole,  $l$ . Find the first integral of the  $\theta$  equation and remove the  $\dot{\theta}$  in the  $r$  equation of motion.

## 1.3 Lagrange Multiplier, $\lambda$

Physically what is the Lagrange multiplier,  $\lambda$ ? In general, is it constant or a function of time? Justify your answer.
